Abstract: This article proves $q$-analogues of classical results for Ehrhart polynomials of Gorenstein polytopes, in the general setting of $q$-Ehrhart polynomials of lattice polytopes. We then study the values on these polynomials of a specific linear form (involving Carlitz’ $q$-analogues of Bernoulli numbers). We also introduce a zeta function associated to an Ehrhart polynomial and connect its evaluation at negative integers to these values.

Keywords: ehrhart polynomial, $q$-analogue, lattice polytope, gorenstein polytope, dirichlet series, bernoulli number

Introduction

This article studies a $q$-Ehrhart polynomial of Gorenstein lattice polytopes. Fixing a specific linear form on the set of polynomials we find an interesting relationship to a certain Dirichlet series, especially its values at negative integers. On the other hand, the initial motivation was to understand something rather different. Let us start with a short account of this story.

It has proved useful and interesting to consider, as a kind of non-associative analogue of usual formal series in one variable, certain formal sums of rooted trees
with coefficients in a base ring. The rooted trees are the analogue of the monomials $x^n$ for formal series. These objects can be multiplied and composed, which then gives a ring like structure similar to formal power series. It is therefore quite natural to call them tree-indexed series. The algebraic side of this theory is described using pre-Lie algebras [4, 7, 13], which are directly related to the geometry of affine structures on manifolds. Tree-indexed series are also used in numerical analysis, where they are called B-series or Butcher series (see [12, Ch. III], [5]), for the study of Runge-Kutta methods.

There are two tree indexed series that play a role similar to that of the exponential and logarithm power series for formal series. The analog of the exponential series we denote by $A$. There is a very simple and pretty formula for its coefficients which are all positive rationals [8, 9]. On the contrary, the analog of the logarithm series, denoted by $\Omega$, has a very complicated set of rational coefficients with signs, some of which vanish.

One intriguing problem is to understand for which trees $T$ does the corresponding coefficient $\Omega_T$ vanish. It is precisely here that the Ehrhart polynomials enters the picture, since it is known [9, 17] that the coefficient $\Omega_T$ of a tree $T$ can always be expressed by using the Ehrhart polynomial of a polytope attached to $T$.

After looking closely at the trees with vanishing coefficients, we observed that most (but not all) of them satisfy a very special property. That is, all their leaves have the same height. It turns out that this property implies that the associated polytope is Gorenstein. This was the starting point of the present article.

Having detected the presence of Gorenstein polytopes in the original problem of when $\Omega_T$ vanishes, we were able to reduce this problem to one that asks when a certain linear form $\Psi$ vanishes on the product of two Ehrhart polynomials determined by two $r$-Gorenstein polytopes of odd total dimension.

A clearer way to express this vanishing property can then be given by replacing an Ehrhart polynomial by a $q$-Ehrhart polynomial, introduced in [10]. In this new context, the vanishing property can now be reformulated to assert that the values of the linear form $\Psi$ are, up to sign, self-conjugate elements of the fraction field $\mathbb{Q}(q)$. Here self-conjugate means invariant under the replacement of $q$ by $1/q$.

The actual vanishing property that interests us occurs by specializing the value of $q$ to equal 1. Seen from this newer perspective, we then observed that this property is quite similar to the vanishing of the Bernoulli numbers of odd indices, which, as is well known, can be proved as a consequence of the functional equation
of the Riemann $\zeta$ function. This led us to look for a zeta function analogy with the hope that we could prove the vanishing property by means of some type of functional equation satisfied by some Dirichlet series. We introduce our candidate for such a series in the last section of the article. Although we are not yet able to prove a functional equation that achieves our goal, we are able to describe both its analytic continuation to the complex plane and give simple expressions of its values at negative integers in term of the linear form $\Psi$.

Let us now describe the contents of this article.

In section 1, we state a simple symmetry property of the $q$-Ehrhart polynomials of Gorenstein polytopes.

Sections 2 and 3 construct the basic objects we subsequently use. Section 2 introduces the $q$-analog of the space of one variable formal power series, as well as several subspaces and bases that are convenient to work with. Section 3 introduces a linear operator $\Sigma$ and two linear forms $V$ and $\Psi$ on these spaces, computes some of their values, and also explains the relation of $\Psi$ to some $q$-analogues of Bernoulli numbers due to Carlitz.

Section 4 contains the main results about $q$-Ehrhart polynomials. We first derive a symmetry property for the coefficients of the $q$-Ehrhart polynomials of Gorenstein polytopes, when expressed in a particular basis. This statement is a natural $q$-analog of the well-known symmetry of the coefficients of the numerator of the Ehrhart series of Gorenstein polytopes. Using this symmetry, we then prove that the image by $\Psi$ of the product of two Ehrhart polynomials of $r$-Gorenstein polytopes is (up to sign) self-conjugate. A similar result is obtained in the special case of 1-Gorenstein (a.k.a. reflexive) polytopes.

In section 5, we set $q = 1$, which returns us to the classical setting of Ehrhart polynomials. We first show that a vanishing result for the coefficients $\Omega_T$ is an easy consequence of the main results proved in Section 4. This is also illustrated by several examples. We also propose a conjecture about what happens when one considers the powers of the Ehrhart polynomial $E_P$ of a single Gorenstein polytope $P$. The sequence $\left(\Psi(E_P^k)\right)_{k \geq 0}$ of rational numbers thus obtained seems to share properties with the Bernoulli numbers. This suggests that it may be useful to think of them as the values at negative integers of a zeta function, in analogy with the classical relation between Bernoulli numbers and Riemann zeta function. It is for this reason that we introduce a Dirichlet series attached to any Ehrhart polynomial. We are not aware of this series having been introduced earlier in the literature.
In the last section 6, we prove two properties about such zeta functions. The first is that the Dirichlet series has a meromorphic continuation to $\mathbb{C}$ with a single pole at $s = 1$ that is simple. The second is that the values at any negative integer $m = 1 - k$ of this meromorphic function is indeed equal to the rational number $-\Psi(E_k^E)/k$ derived from the sequence above.

Many thanks to Eric Delaygue, Frédéric Jouhet, Philippe Nadeau and Tanguy Rivoal for useful discussions and helpful explanations about some delicate features of hypergeometric series. Many thanks also to Ben Lichtin for his suggestions which allowed us to improve the presentation of the introduction of this paper.

**Notations**

Let us introduce some basic notations. The letter $q$ will always stand for a formal parameter. It will either be considered as an element of $\mathbb{Q}(q)$ or as an element of $\mathbb{Z}[q, 1/q]$.

For $n \in \mathbb{N}$, we will denote by $[n]_q$ the $q$-integer $1 + q + \ldots + q^{n-1}$. Using instead the formula $q^{-1}q^{n-1}$, this can be extended to $n \in \mathbb{Z}$. One then has the obvious relations $[n]_{1/q} = q^{n+1}[n]_q$ and $[-n]_q = -q^{-n}[n]_q$.

For $n \in \mathbb{N}$, we will denote by $[n]_q!$ the $q$-factorial of $n$, namely the product $[1]_q[2]_q \ldots [n]_q$.

For $m, n \in \mathbb{N}$, we will denote by $\binom{m}{n}_q$ the $q$-binomial $\frac{[m]_q!}{[n]_q![m-n]_q!}$.

For fixed $n \in \mathbb{N}$, this can be written as $\binom{[m]_q[m-1]_q \ldots [m-n+1]_q}{[n]_q!}$, which makes sense for every $m \in \mathbb{Z}$. One then has the useful formulas $\binom{-m}{n}_q = (-1)^n q^{-nm-\binom{n}{2}} \binom{m+n-1}{n}_q$ and $\binom{m}{n}_{1/q} = q^{-m(n-m)} \binom{-m}{n}_q$.

All the previous notations are rather standard for these $q$-analogues. We will need also some other notations, less classical.

For $n \in \mathbb{N}$, let $[n, x]_q$ be the polynomial $[n]_q + qx$. For $m, n \in \mathbb{N}$, let us also define the polynomial $\binom{m, x}{n}_q = \frac{[m-n+1, x]_q[m-n+2, x]_q \ldots [m, x]_q}{[n]_q!}$.

When $q$ is replaced by 1, they become $n + x$ and $\binom{m+x}{n}$.

These polynomials are defined in this way so that they have nice evaluations when $x$ is replaced by a $q$-integer $[k]_q$. Indeed $[n, [k]_q]_q$ is just $[n + k]_q$ and therefore $\binom{m, [k]_q}{n}_q = \binom{m+k}{n}_q$.
They also satisfy the following translation properties:

\[ [n, [k, x]_q]_q = [n + k, x]_q \quad \text{and} \quad \left[ \frac{m}{n} [k, x]_{\frac{1}{q}} \right]_q = \left[ \frac{m + k}{n} \right]_q. \]

1. On \textit{q-Ehrhart polynomials of Gorenstein polytopes}

We will use here some results of the article [10], where a \textit{q}-analogue of the classical theory of Ehrhart polynomials has been introduced.

Recall that a lattice polytope \( P \) is called \textit{reflexive} if it contains the lattice origin \( 0 \) and the dual polytope \( P^* \) is also a lattice polytope. These polytopes are used in the study of mirror symmetry in the setting of toric geometry. There is another closely related notion. A lattice polytope \( P \) is called \textit{r-Gorenstein} (for some integer \( r \geq 1 \)) if the dilated polytope \( rP \) is (up to lattice translation) reflexive.

For more on reflexive and Gorenstein polytopes, the reader can consult for example [1, 2, 14–16].

Let us now assume that \( P \) is an \textit{r-Gorenstein} lattice polytope of dimension \( D \). Let \( z_0 \) be the unique interior lattice point of \( rP \).

Let \( \lambda \) be a linear form on the lattice, such that \( \lambda \) is positive on \( P \) and \( \lambda \) is not constant on any edge of \( P \). These conditions are required for the definition of the \textit{q-Ehrhart polynomial} (see [10] for details).

Then we can consider the \textit{q-Ehrhart polynomial} \( E_{P, \lambda}(x, q) \), defined by

\[ E_{P, \lambda}([n]_q, q) = \sum_{s \in \mathbb{N}^P} q^{\lambda(s)}. \] \hspace{1cm} (1.1)

For short, it will be denoted by \( E \) when no ambiguity is possible. This is a polynomial in \( \mathbb{Q}(q)[x] \).

Our first result is the following simple symmetry property.

\textbf{Proposition 1.} \textit{The \textit{q-Ehrhart polynomial} \( E \) satisfies}

\[ E(x, q) = (-1)^D E(-q[r, x]_q, 1/q) q^{-\lambda(z_0)}. \] \hspace{1cm} (1.2)

This is a \textit{q}-deformation of the classical relation

\[ E(x) = (-1)^D E(-r - x) \] \hspace{1cm} (1.3)

for the Ehrhart polynomial of \( r \)-Gorenstein lattice polytopes.
PROOF. Let \( n \geq 1 \) be an integer. By \( q \)-Ehrhart reciprocity [10, Th. 2.5], we know that

\[
E([-n]_q, q) = (-1)^D \sum_{s \in \text{Im}(nP)} q^{-\lambda(s)}.
\]

By the Gorenstein property, the translation by the vector \( z_0 \) gives an isomorphism of lattice polytopes from \( nP \) to \( \text{Int}((n + r)P) \). It follows that

\[
E([-n - r]_q, q) = (-1)^D \sum_{s \in nP} q^{-\lambda(s + z_0)},
\]

whose right hand side can be written as

\[
(-1)^D E([-n]_q, q) \bigg|_{q=1/q} q^{-\lambda(z_0)} = (-1)^D E([-n]_{1/q}, 1/q)q^{-\lambda(z_0)}.
\]

Then consider the variables

\[
x = [-n - r]_q, \quad X = [n]_{1/q}.
\]

One can check that they are related by \( X = -q[r, x]_q \). The statement follows. \( \square \)

Note that the product \( P \times Q \) of two \( r \)-Gorenstein polytopes is still an \( r \)-Gorenstein polytope. Moreover, the \( q \)-Ehrhart polynomial of a product \( P \times Q \) of polytopes, with respect to the linear form \( \lambda \oplus \mu \), is the product \( E_{P,\lambda} E_{Q,\mu} \). This is obviously compatible with the proposition.

If \( P \) is a polytope, let us call the pyramid over \( P \) the convex hull of \((0, 0)\) and \( 1 \times P \) in a lattice of one more dimension. The pyramid over an \( r \)-Gorenstein polytope is an \( r + 1 \)-Gorenstein polytope.

2. Binomial bases for polynomials in \( x \)

Let us now consider the polynomial ring \( \mathbb{Q}(q)[x] \) and some of its elements.

This ring has a basis over \( \mathbb{Q}(q) \) given by the polynomials \( \left[ \frac{n}{x} \right]_q \) for \( n \geq 0 \), which will be called the \( B \)-basis.

Let us now define \( A_q \), as the subspace of \( \mathbb{Q}(q)[x] \) generated over \( \mathbb{Z}[q, 1/q] \) by the polynomials \( \left[ \frac{n}{x} \right]_q \).

For an integer \( d \in \mathbb{N} \), let us denote by \( A_q^{(d)} \) the subspace of \( A_q \) of polynomials of degree at most \( d \).
Proposition 1. The polynomials $\binom{k, x}{d}_q$ for $k = 0, \ldots, d$ form a basis of $A_q^{(d)}$ over $\mathbb{Z}[q, 1/q]$.

Proof. This follows from lemma 1, which proves that the matrix of coefficients of these polynomials in the $B$-basis is triangular with powers of $q$ on the diagonal. □

Lemma 1. For integers $0 \leq i \leq d$, there holds

$$\binom{i, x}{d}_q = \sum_{j=0}^{d} (-1)^{d-j} q^{-d(d-i)+\binom{d-j}{d-i}} \binom{j, x}{d-j}_q.$$

Proof. It is enough to check this for all $q$-integers $[k]_q$. This becomes

$$\binom{i+k}{d}_q = \sum_{j=0}^{d} (-1)^{d-j} q^{-d(d-i)+\binom{d-j}{d-i}} \binom{j+k}{j}_q.$$

This is an instance of the $q$-Chu-Vandermonde formula for the $2\phi_1$ basic hypergeometric function, see for example [11, Appendix II, formula (II.7)]. □

Let us now describe the product in this basis.

Proposition 2. For all integers $0 \leq i \leq d$ and $0 \leq j \leq e$, there holds

$$\binom{i, x}{d}_q \cdot \binom{j, x}{d}_q = \sum_{0 \leq \ell \leq d+e} q^{(\ell-e-i)(\ell-d-j)} \binom{\ell, x}{d+e}_q.$$

Proof. As this is an equality of polynomials in $x$, it is enough to check that it holds for all positive $q$-integers, namely that

$$\binom{i+k}{d}_q \cdot \binom{j+k}{d}_q = \sum_{0 \leq \ell \leq d+e} q^{(\ell-e-i)(\ell-d-j)} \binom{\ell, x}{d+e}_q$$

holds for all $k \geq 0$. This equality is in fact an instance of the classical Pfaff-Saalschütz identity for the basic hypergeometric function $3\phi_2$. It can be recovered for example by letting $d = -j, a = e + i, e = -i, b = d + j, c = -k - 1$ in formula (4) of [18]. □

Proposition 1 and 2 together implies that the subspace $A_q$ of $\mathbb{Q}(q)[x]$ is a commutative ring over $\mathbb{Z}[q, 1/q]$. 

Let us now turn to a simple symmetry statement, for later use.

**Proposition 3.** For all integers \( d, r, k \), the polynomials \( \left[ \frac{k}{d}, x \right]_q \) have the following symmetry property:

\[
\left[ \frac{k-q[r,x]}{d} \right]_{1/q} = (-1)^d q^{d+1} \left[ \frac{r-1+d-k}{d} \right]_q.
\] (2.3)

**Proof.** This is a simple computation using the definition of these polynomials. The left hand side is

\[
\frac{[k-d+1, y]_{1/q} \ldots [k, y]_{1/q}}{[1]_{1/q} \ldots [d]_{1/q}}
\]

with \( y = -q[r, x]_q \). This can be rewritten as

\[
\frac{q^{d-k}([k-d+1]_q - [r, x]_q) \ldots q^{-k}([k]_q - [r, x]_q)}{q^0[1]_{q} \ldots q^{-d+1}[d]_q}.
\]

This becomes

\[
(-1)^d q^{(\frac{d}{q})} q(q^{r-1+d-k} x + [r - 1 + d - k]_q) \ldots q^{(q^{-k} x + [r - k]_q)} [d]_q,
\]

which gives the expected result. □

### 3. Operator and linear forms

Let us define an endomorphism \( \Sigma \) of \( \mathbb{Q}(q)[x] \) by

\[
(\Sigma E)([n]_q) = \sum_{j=0}^{n} q^j E([j]_q),
\] (3.1)

for all polynomials \( E \).

If \( E \) is the \( q \)-Ehrhart polynomial \( E_{P,\lambda} \) of a polytope \( P \) and linear form \( \lambda \), then \( \Sigma E \) is the \( q \)-Ehrhart polynomial of the pyramid over \( P \) as defined at the end of section 1, with the linear form \( 1 \oplus \lambda \).

**Lemma 2.** For every integer \( d \geq 0 \), there holds

\[
\Sigma \left[ \frac{d}{q}, x \right] = \left[ \frac{d+1}{d+1}, x \right]_q.
\] (3.2)
Proof. As an equality between polynomials in \( x \), it is enough to check that it holds for every positive \( q \)-integer \( k \). This becomes

\[
\sum_{j=0}^{k} q^j \left[ \binom{d+j}{d} \right]_q = \left[ \binom{d+1+k}{d+1} \right]_q.
\]

This is a classical formula, which has a simple combinatorial proof using the description of \( q \)-binomials by paths in a rectangle according to their area. \( \square \)

Note that property (3.2) uniquely defines the linear operator \( \Sigma \). This also proves that it acts on the subring \( A_q \).

**Lemma 3.** For all integers \( i \) and \( d \) with \( 0 \leq i \leq d \), there holds

\[
\Sigma \left[ \binom{i}{d} \right]_q = q^{d-i} \left( \binom{i+1}{d+1} q - \binom{i}{d+1} q \right). \tag{3.3}
\]

**Proof.** To prove this equality of polynomials in \( x \), it is enough to check the statement for every positive \( q \)-integer \([k]_q\). This becomes

\[
\sum_{j=0}^{k} q^j \left[ \binom{i+j}{d} \right]_q = q^{d-i} \left( \binom{i+1+k}{d+1} q - \binom{i}{d+1} q \right).
\]

This holds because

\[
\sum_{j=0}^{k} q^{-d} \left[ j \right]_q = \left[ \frac{k+1}{d+1} \right]_q,
\]

which is a classical formula, equivalent to (3). \( \square \)

Let us define next a linear form \( V \) from \( A_q \) to \( \mathbb{Q}(q) \) by

\[
V(E) = \lim_{x \to [-1]_q} \frac{E(x) - E([-1]_q)}{1 + qx}. \tag{3.4}
\]

Note that \([-1]_q = -1/q\). This operator is therefore essentially the derivative of \( E \) at \( x = [-1]_q \), up to a multiplicative factor of \( q \).

Let us now define another linear form \( \Psi \) on \( A_q \) by the composition

\[
\Psi(E) = V \Sigma E. \tag{3.5}
\]
We will later study the values of the linear form \( \Psi \) on the \( q \)-Ehrhart polynomials of Gorenstein polytopes.

Let us first compute the values of \( \Psi \) on the basis elements.

**Proposition 1.** For all integers \( 0 \leq i \leq d \), there holds

\[
\Psi \left( \binom{i}{d} q \right) = \frac{(-1)^{d-i} q^{\binom{d}{2}}}{[d+1]_q [i]_q}. \quad (3.6)
\]

**Proof.** Using formula (3.3), one can compute

\[
\Psi \left( \binom{i}{d} q \right) = q^{d-i} V \left( \binom{i+1}{d+1} q - \binom{i}{d+1} q \right) = q^{d-i} V \left( \frac{[i-d+1, x]_q \cdots [i+1, x]_q}{[d+1]!_q} - \frac{[i-d]_q \cdots [i]_q}{[d+1]!_q} \right).
\]

By definition, the operator \( V \) is proportional to the derivative at \([-1]_q\). This implies that one gets

\[
q^{d-i} \left( [i-d]_q \cdots [-1]_q \right) \left( [1]_q \cdots [i]_q \right)
\]

which can be readily rewritten as the expected result. \( \square \)

From these values, we deduce the following lemma.

**Lemma 4.** For every polynomial \( E \in \mathbb{Q}(q)[x] \), there holds

\[
q \Psi(E(1 + qx)) - \Psi(E) = (q - 1)E(0) + \partial_x E(0). \quad (3.7)
\]

**Proof.** As both sides are linear in \( E \), it is enough to check this identity for every basis element \( E = \binom{d}{d} q \). First note that \( \Psi(E) = \frac{1}{[d+1]_q} \) by proposition 1. Then using (3.3), one computes

\[
q \Psi(E(1 + qx)) = qV \Sigma(E(1 + qx)) = V \left( \binom{d+2}{d+1} - \binom{d+1}{d+1} \right) = V \left( \binom{d+2}{d+1} \right).
\]

By a direct computation using that \( V \) is proportional to the derivative at \([-1]_q\), this is \( \sum_{j=1}^{d+1} \frac{q^j}{[j]_q} \). The same computation gives that \( \partial_x E(0) = \sum_{j=1}^{d} \frac{q^j}{[j]_q} \). The result follows. \( \square \)
Let us now introduce the \( q \)-Bernoulli numbers of Carlitz by the formula

\[
\Psi(x^n) = B_{q,n},
\]

for \( n \geq 0 \).

These rational fractions, introduced by Carlitz in [6], are \( q \)-analogues of the Bernoulli numbers with nice properties. In particular, they only have simples poles at non-trivial roots of unity, and their value at \( q = 1 \) are the classical Bernoulli numbers. To see that (3.8) gives the same definition as Carlitz one, one can use lemma 4 applied to the monomials \( x^n \).

Let us now go back to the study of \( \Psi \). We will need the following result later.

**Proposition 2.** For all integers \( 0 \leq i \leq d \) and \( 0 \leq j \leq e \), there holds

\[
\Psi\left(\left[\begin{array}{c} i \\ d \end{array}\right]_q \left[\begin{array}{c} j \\ e \end{array}\right]_q\right) = \frac{(-1)^{d-i+e-j} q^{-\binom{d-i}{2}+(d-i)(e-j)-\binom{e-j}{2}}}{[d + e + 1]_q\left[\begin{array}{c} d \\ d+i+j \end{array}\right]_q}.
\]

**Proof.** Let us compute \( \Psi\left(\left[\begin{array}{c} i \\ d \end{array}\right]_q \left[\begin{array}{c} j \\ e \end{array}\right]_q\right) \). By proposition 2, this is

\[
\sum_{0 \leq \ell \leq d+e} q^{(\ell - e - i)(\ell - d - j)} \left[\begin{array}{c} d + j - i \\ \ell - i \end{array}\right]_q \left[\begin{array}{c} e + i - j \\ \ell - j \end{array}\right]_q \Psi\left(\left[\begin{array}{c} \ell \\ d + e \end{array}\right]_q\right).
\]

By proposition 1, this is

\[
\sum_{0 \leq \ell \leq d+e} q^{(\ell - e - i)(\ell - d - j)} \left[\begin{array}{c} d + j - i \\ \ell - i \end{array}\right]_q \left[\begin{array}{c} e + i - j \\ \ell - j \end{array}\right]_q \frac{(-1)^{d+e-\ell} q^{-\binom{\ell - e - i}{2}}}{[d + e + 1]_q\left[\begin{array}{c} d + e \\ \ell \end{array}\right]_q}.
\]

Using lemma 5, this becomes the expected result. \( \square \)

**Lemma 5.** Let \( 0 \leq i \leq d \) and \( 0 \leq j \leq e \) be integers. Then

\[
\sum_{0 \leq \ell \leq d+e} (-1)^\ell q^{(\ell - e - i)(\ell - d - j)-\binom{\ell - e - i}{2}} \frac{\binom{\ell}{d}}{\binom{d+e}{\ell}} = (-1)^{i+j} q^{-\binom{d-i}{2}+(d-i)(e-j)-\binom{e-j}{2}} \frac{\binom{d}{d}}{\binom{d+e}{d}}.
\]

**Proof.** One can assume without loss of generality that \( i \geq j \). This can then be reformulated as an hypergeometric identity for the function \( _3\phi_2 \). This formula can be deduced from [11, Appendix III, formula (III.10)]. \( \square \)
4. Symmetry of coefficients and self-conjugate values

Let $P$ be an $r$-Gorenstein lattice polytope of dimension $D$. Let $E(x, q)$ be its $q$-Ehrhart polynomial with respect to a linear form $\lambda$.

Let $d$ be the degree of $E(x, q)$. Using proposition 1, let us write $E(x, q)$ as follows:

$$E(x, q) = \sum_{j=0}^{d} c_j \left[ \frac{j}{d} \right] x^d,$$  \quad (4.1)

for some coefficients $c_j$ in $\mathbb{Q}(q)$.

**Proposition 1.** The coefficients $c_k$ vanish for $0 \leq k \leq r - 2$. Moreover

$$c_k = (-1)^{D+d} q^{\binom{d+1}{2} - \lambda(z_0)} c_{r-1+d-k} (1/q).$$  \quad (4.2)

**Proof.** Because $P$ is an $r$-Gorenstein polytope, the dilated polytopes $kP$ have an empty interior if $1 \leq k \leq r - 1$. This implies that $E(x, q)$ vanishes at the $q$-integers $[-1]_q, \ldots, [1-r]_q$. This in turn implies the vanishing of the coefficients $c_0, \ldots, c_{r-2}$ (by an easy induction).

Let us now show that the symmetry property of proposition 3 together with the symmetry property of proposition 1 implies the expected symmetry of the coefficients. One computes

$$(-1)^D E(-q[r, x]q^{1/q}) q^{-\lambda(z_0)} = (-1)^D \sum_{k=r-1}^{d} c_k (1/q) \left[ k, \frac{-q[r,x]}{d} \right] q^{-\lambda(z_0)} =$$

$$= (-1)^D \sum_{k=r-1}^{d} c_k (1/q) (-1)^d q^{\binom{d+1}{2}} \left[ \frac{r-1+d-k}{d} \right] q^{-\lambda(z_0)} =$$

$$= (-1)^D \sum_{k=r-1}^{d} c_{r-1+d-k} (1/q) (-1)^d q^{\binom{d+1}{2}} \left[ \frac{k}{d} \right] q^{-\lambda(z_0)}.$$  \quad (4.3)

One then identifies the coefficients with (4.1) to get the expected equality. \hfill \Box

This statement is a $q$-analogue of the usual symmetry $c_k = (-1)^{D+d} c_{r-1+d-k}$ for $r$-Gorenstein polytopes. In the classical setting, the numbers $c_k$ are the coefficients of the numerator of the Ehrhart series ($h$-vector).
Let now \( r \geq 1 \) be a fixed integer. Let \( P \) and \( Q \) be two \( r \)-Gorenstein lattice polytopes of dimensions \( D \) and \( E \). Let \( E_P \) and \( E_Q \) be their \( q \)-Ehrhart polynomials with respect to some linear forms \( \lambda \) and \( \mu \) (omitted to keep the notation short). Let \( d \) and \( e \) be the degrees of these polynomials.

Let us introduce the shortcuts \( Z = \lambda(z_0) \) and \( Z' = \mu(z'_0) \) where \( z_0 \) and \( z'_0 \) are the unique interior points in the dilated polytopes \( rP \) and \( rQ \). Let us write

\[
E_p = \sum_{0 \leq i \leq d} c_i^{[i,x]}_d q \quad \text{and} \quad E_Q = \sum_{0 \leq j \leq e} c'_j^{[j,x]}_e q. \tag{4.4}
\]

Let \( s_{-k} \) be the shift (with offset \(-k\)) defined by \( s_{-k}(P)([n]_q) = P([n - k]_q) \) for all \( n \in \mathbb{Z} \) or equivalently by \( (s_{-k}P)(x) = P([-k, x]) \). Then one has

\[
s_{-k}E_p = \sum_{0 \leq i \leq d} c_{i+k}^{[i,x]}_d q \quad \text{and} \quad s_{-k}E_Q = \sum_{0 \leq j \leq e} c'_{j+k}^{[j,x]}_e q, \tag{4.5}
\]

for all \( 0 \leq k \leq r - 1 \) (using the vanishing statement in proposition 1).

**Theorem 1.** Let \( 0 \leq k \leq r - 1 \) and let \( F(q) \) be the fraction \( q^{-k}\Psi(s_{-k}(E_PE_Q)) \). Then

\[
F(1/q) = (-1)^{D+E} q^{Z+Z'+r-1} F(q).
\]

**Proof.** Let us first compute \( \Psi(s_{-k}(E_PE_Q)) \) using the expressions (4.4) and proposition 2. One gets

\[
\frac{(-1)^{d+e}}{[d + e + 1]_q} \sum_{i,j} (-1)^{i+j} c_{i+k}^{(i+j)}_{d} q^{-(\frac{d-e}{2})+(d-i)(e-j)-(\frac{e-j}{2})} \left[ \frac{d+e}{d-i+j} \right]_q.
\]

Let us now replace \( q \) by \( 1/q \) in this expression. One gets

\[
\frac{(-1)^{d+e}}{[d + e + 1]_q} \sum_{i,j} (-1)^{i+j} c_{i+k}(1/q) c'_{j+k}(1/q) q^{(\frac{d}{2})-(d-i)(e-j)+(\frac{e}{2})} \left[ \frac{d+e}{d-i+j} \right]_{1/q}.
\]
Using (4.2) once for $P$ and once for $Q$, this becomes

\[
\frac{(-1)^{D+E}q^{d+e}}{[d + e + 1]_q} \sum_{i,j} (-1)^{i+j}c_{r-1+d-i-k}e_{r-1+e-j-k} \times \\
q^{\left(\binom{d-i}{2} - (d-i)(e-j) + \binom{d+i}{2} + Z + \binom{e+j}{2} + Z' + (d-i+j)(e-j+i) \right)} \left[\frac{d+e}{d-i+j} \right]_q.
\]

Changing the indices of summations $i \mapsto r-1+d-i-2k$ and $j \mapsto r-1+e-j-2k$, one gets (after simplifications in the powers of $q$)

\[
\frac{q^{-2k}q^{Z+Z'}+r-1(-1)^{D+E}}{[d + e + 1]_q} \sum_{i,j} (-1)^{d-i+e-j}c_{i+k}e_{j+k} \times q^{\left(\binom{d-i}{2} + (d-i)(e-j) - \binom{e+j}{2} \right)} \left[\frac{d+e}{e+i-j} \right]_q.
\]

Up to the power of $q$ in front of the sum, this is $(-1)^{D+E}$ times the initial expression for $\Psi(s_{-k}(E_P E_Q))$. □

In the special case of reflexive (i.e. 1-Gorenstein) polytopes, it is not necessary to consider a product of two polytopes to obtain a similar result. Let us now assume that $P$ is reflexive.

**Theorem 2.** Let $F(q)$ be the fraction $\Psi(E_P)$. Then

\[
F(1/q) = (-1)^{D}q^Z F(q).
\]

**Proof.** Let us first compute $\Psi(E_P)$ using the expression (4.4) for $P$ and proposition 1. One gets

\[
\frac{(-1)^d}{[d + 1]_q} \sum_{i} (-1)^i c_i q^{-\binom{d}{2}} \left[\frac{d}{i} \right]_q.
\]

Let us now replace $q$ by $1/q$ in this expression. One gets

\[
\frac{(-1)^d}{[d + 1]_{1/q}} \sum_{i} (-1)^i c_i (1/q) q^{\binom{d-i}{2}} \left[\frac{d}{i} \right]_{1/q}.
\]
Using (4.2) for $P$ (and the hypothesis $r = 1$), this becomes

$$
\frac{(-1)^D q^d}{[d + 1]_q} \sum_i (-1)^i c_{d-i} q^{\binom{d+i}{2} - \binom{d+i}{2} + i(d-i)} [\frac{d}{i}]_q.
$$

Changing the index of summation $i \mapsto d - i$, one gets (after simplifications in the powers of $q$)

$$
q^Z \frac{(-1)^D}{[d + 1]_q} \sum_i (-1)^{d-i} c_i q^{-\binom{i}{2}} [\frac{d}{i}]_q.
$$

Up to the power $q^Z$ in front of the sum, this is $(-1)^D$ times the initial expression for $\Psi(E_P)$. □

In fact, the self-conjugate fractions involved in theorem 1 are all the same. Keeping the same notations, we have the following result.

**Proposition 2.** The fractions $q^{-k}\Psi(s_{-k}(E_P E_Q))$ for $k = 0, 1, \ldots, r - 1$ are all equal.

**Proof.** Let us apply lemma 4 to the polynomial $s_{-k}(E_P E_Q)$ for $k = 1, \ldots, r - 1$. One gets

$$
q^k \Psi(s_{1-k}(E_P E_Q)) - \Psi(s_{-k}(E_P E_Q)) = (q - 1) E_P([-k]_q) E_Q([-k]_q) + q^{-k} \partial_x E_P([-k]_q) E_Q([-k]_q) + q^{-k} E_P([-k]_q) \partial_x E_Q([-k]_q).
$$

Because of the $r$-Gorenstein property, the right hand side vanishes for $k = 1, \ldots, r - 1$. This implies the statement. □

5. Classical case $q = 1$

One can state purely classical corollaries of theorems 1 and 2 by letting $q = 1$. The $q$-Ehrhart polynomial becomes the Ehrhart polynomial, and does no longer depend on the choice of a linear form $\lambda$.

In this context, $\Psi$ becomes the linear form on the space $\mathbb{Q}[x]$ that maps $x^n$ to the Bernoulli number $B_n$. The operator $s_{-k}$ becomes the evaluation of polynomials in $x$ at $x - k$. We obtain the following statements.
Theorem 3. Let $P$ be a product of at least two $r$-Gorenstein polytopes. Let $E_P$ be its Ehrhart polynomial. The numbers $\Psi(s_k E_P)$ for $k = 0, 1, \ldots, r - 1$ are all equal. If moreover the dimension of $P$ is odd, then they all vanish.

Theorem 4. Let $P$ be a reflexive polytope. Let $E_P$ be its Ehrhart polynomial. If the dimension of $P$ is odd, then $\Psi(E_P) = 0$.

Let us now consider some simple examples.

Let $P$ be the polytope with vertices 0 and 1 in $\mathbb{Z}$. This is a 2-Gorenstein polytope, with Ehrhart polynomial $x + 1$. We deduce from theorem 3 that $\Psi((x + 1)^n) = 0$ for all odd $n \geq 3$. By definition of the Bernoulli numbers, the expression $\Psi((x + 1)^n)$ is just $B_n$ itself, which is well-known to vanish in this case.

Let now $P$ be the polytope with vertices 0 and 2 in $\mathbb{Z}$. This is a reflexive polytope (up to translation), with Ehrhart polynomial $1 + 2x$. Therefore theorem 4 implies that $\Psi(1 + 2x) = 0$, which is indeed the case because $B_0 = 1$ and $B_1 = -1/2$.

Let us consider a more complicated example. There exists a reflexive simplex in dimension 5 with 355785 lattice points [14]. Its Ehrhart polynomial is $E = 271803x^5/5 + 271803x^4/2 + 118594x^3 + 83979x^2/2 + 24692x/5 + 1$. One can check directly that its image by $\Psi$ vanishes, as well as the images by $\Psi$ of its small odd powers. By contrast, the even values do not vanish, for example $\Psi(E^2) = -48827203879/165$.

As an interesting counter-example, consider the triangle in $\mathbb{Z}^2$ with vertices $(0, 0)$, $(1, 0)$ and $(1, 1)$. The Ehrhart polynomial is $E = \binom{x+2}{2}$. The first few values of $\Psi(E^i)$ are given by

$$1, 1/3, 1/30, -1/105, 1/210, -1/231, 191/30030, -29/2145, 2833/72930, \ldots \quad (5.1)$$

There is no vanishing here, as this polytope is 3-Gorenstein, but not a product of two such polytopes. One can note that these coefficients have appeared in the work of Ramanujan, in an asymptotic formula involving triangular numbers (see number (9) of [3, Chapter 38]).

### 5.1. Bernoulli-like numbers attached to Gorenstein polytopes

Let $P$ be an $r$-Gorenstein polytope of odd dimension $D$ and let $E_P$ be its Ehrhart polynomial. As a special case of theorem 3, the rational numbers $\Psi(E_P^k)$
attached to the powers $E^k_P$ vanish for every odd integer $k \geq 3$. This can be seen as an analog of the same statement for Bernoulli numbers.

This suggest, for any fixed $r$-Gorenstein polytope $P$, to think about the sequence $\Psi(E^k_P)_{k \geq 0}$ as some kind of Bernoulli-like numbers attached to the Gorenstein polytope $P$.

It seems that at least one other property of Bernoulli numbers extends to the Bernoulli-like numbers, namely the following alternating sign property, which is is well-known for the Bernoulli numbers.

**Conjecture 1.** If the dimension of $P$ is odd, the signs of the non-zero $\Psi(E^k_P)$ alternate.

For example, consider the 3-dimensional simplex with vertices $(0, 0, 0)$, $(1, 0, 0)$, $(1, 1, 0)$ and $(1, 1, 1)$. Its Ehrhart polynomial is $E = \binom{x+3}{3}$. The first few values of $\Psi(E^k)$ are

$$
1, 1/4, 1/140, 0, -41/60060, 0, 50497/19399380, 0,
$$
$$
-13687983/148728580, 0, 485057494433/30855460020, \ldots
$$

In the case of even dimension, it seems also that the signs are alternating, see for example (5.1).

These alternating conjectures are related to the behavior of the number of zeroes in $[0, 1]$ of the $q$-analogues of these numbers and to the next topic, namely continuous interpolation of the Bernoulli-like numbers by zeta-like functions.

### 5.2. Zeta functions of polynomials

Given a polynomial $E$ in $\mathbb{Q}[x]$ taking positive values on $\mathbb{N}$, one can consider a kind of zeta function attached to $E$, defined by

$$
Z(E; s) = \sum_{n \geq 0} \frac{\partial_x E(n)}{E(n)^s},
$$

for complex numbers $s$ with $\Re(s) > 1$.

We will be mostly interested in the case where $E$ is the Ehrhart polynomial of a lattice polytope $P$. For example, one gets in this way

$$
\sum_{n \geq 0} \frac{1}{(1 + n)^s} = \zeta(s) \quad \text{and} \quad \sum_{n \geq 0} \frac{2}{(1 + 2n)^s} = 2(1 - 2^{-s})\zeta(s)
$$

for the two Gorenstein polytopes of dimension 1.
We show in the next section that under some mild hypotheses on \( E \) the function \( Z(E; s) \) is a meromorphic function of the complex parameter \( s \) with only a single pole at 1 with residue 1. Moreover its values at negative integers are given in terms of \( \Psi \) and \( E \) by the formula

\[
Z(E; 1 - k) = -\frac{\Psi(E^k)}{k}
\]

for all \( k \in \mathbb{N}^* \).

Before proving this in the next section, let us give an heuristic argument. By letting \( q = 1 \) in lemma 4, one gets

\[
\Psi(E(1 + x)) - \Psi(E) = \partial_x E(0).
\]

After a telescoping summation, one gets

\[
\Psi(E(\ell + x)) - \Psi(E) = \sum_{j=0}^{\ell-1} \partial_x E(j)
\]

For polynomials that are powers (of the shape \( F^k \) for some \( F \)), one therefore gets

\[
\Psi(F(\ell + x)^k) - \Psi(F^k) = k \sum_{j=0}^{\ell-1} \partial_x F(j) F(j)^{k-1}.
\]

Formally going to the limit \( \ell = \infty \) (and assuming that the first term of the left-hand side disappears) gives formula (5.4).

6. Study of zeta-like functions

Let \( (B_k)_{k \geq 0} \) be the sequence of Bernoulli numbers. Recall the linear operator \( \Psi : \mathbb{C}[X] \to \mathbb{C} \) defined by

\[
\Psi(X^k) = B_k \quad \forall k \in \mathbb{N}.
\]

By the usual properties of Bernoulli numbers, there also holds

\[
\Psi((X + 1)^k) = (-1)^k B_k \quad \forall k \in \mathbb{N}.
\]
For all \( x = (x_1, \ldots, x_d) \in \mathbb{R}^d \) and all \( \alpha = (\alpha_1, \ldots, \alpha_d) \in \mathbb{N}^d \), we will use in the sequel the following notations: \( x^\alpha = x_1^{\alpha_1} \cdots x_d^{\alpha_d} \) and \( |\alpha| = \alpha_1 + \cdots + \alpha_d \). We denote also for any \( z \in \mathbb{C} \) verifying \( \text{Re} z > 0 \) and any \( s \in \mathbb{C} \), \( z^s = e^{s \log x} \) where \( \log \) is the principal determination of the logarithm.

The purpose of this section is to prove the following result:

**Theorem 5.** Let \( E \in \mathbb{R}[X] \) be a polynomial of degree \( d \geq 1 \). Let \( a_1, \ldots, a_d \in \mathbb{C} \) be the roots (not necessarily distinct) of \( E \). Let \( A \in \mathbb{N}^d \) be such that \( \forall x \geq A \ \text{Re} E(x) > 0 \). We consider the Dirichlet series

\[
Z_A(E; s) := \sum_{n=A}^{+\infty} \frac{E'(n)}{E(n)^s}.
\]

Then:

(i) \( s \mapsto Z_A(E; s) \) converges absolutely in the half-plane \( \{\text{Re}(s) > 1\} \) and has a meromorphic continuation to the whole complex plane \( \mathbb{C} \);

(ii) the meromorphic continuation of \( Z_A(E; s) \) has only one simple pole in \( s = 1 \) with residue 1;

(iii) for any \( M \in \mathbb{N}^d \), \( Z_A(E; 1 - M) = -\frac{1}{M} \Psi(E(X + 1)^M) - \sum_{n=1}^{A-1} E(n)^{M-1} E'(n) \).

**Remark 6.1.** By taking \( A = 1 \) and using the shifted polynomial \( E(X - 1) \) in the previous theorem, point 3 gives the formula (5.4). Note that summation in \( Z_1(E(X - 1); s) \) starts at 1, whereas summation in (5.2) starts at 0.

We need the following elementary lemma:

**Lemma 6.** Let \( d \in \mathbb{N}^d \) and \( a = (a_1, \ldots, a_d) \in \mathbb{N}^d \setminus \{(0, \ldots, 0)\} \). Set \( \delta = (2 \max_j |a_j|)^{-1} > 0 \). Then, for any \( N \in \mathbb{N} \), any \( s = (s_1, \ldots, s_d) \in \mathbb{C}^d \) and any \( x \in [-\delta, \delta] \), one has

\[
\prod_{j=1}^{d} (1 - xa_j)^{-s_j} = \sum_{\ell=0}^{N} c_\ell(s) \ x^\ell + x^{N+1} \rho_N(x; s)
\]

where

\[
c_\ell(s) = (-1)^\ell \sum_{\alpha \in \mathbb{N}^d \setminus \{0\}, |\alpha| = \ell} a^\alpha \prod_{j=1}^{d} \binom{-s_j}{\alpha_j}.
\]
\[ \rho_N(x; s) = (-1)^{N+1}(N+1) \sum_{\alpha \in \mathbb{N}^d \atop |\alpha| = N+1} a^\alpha \prod_{j=1}^d \left( \frac{-s_j}{\alpha_j} \right) \int_0^1 (1-t)^N \prod_{j=1}^d (1-t x a_j)^{-s_j-\alpha_j} \, dt. \]

Moreover one has:

(i) for any \( x \in [-\delta, \delta] \), \( s \mapsto \rho_N(s; x) \) is holomorphic in the whole space \( \mathbb{C}^d \);

(ii) for any compact subset \( K \) of \( \mathbb{C}^d \), there exists a constant \( C = C(K, a, N, d) > 0 \) such that

\[ \forall (s, x) \in K \times [-\delta, \delta] \quad |\rho_N(s; x)| \leq C. \]

**Proof.** Let us fix \( s \in \mathbb{C}^d \). We consider the function \( \phi \) defined in \( [-\delta, \delta] \) by \( \phi(x) = \prod_{j=1}^d (1-x a_j)^{-s_j} \). The function \( \phi \) is infinitely differentiable in \( [-\delta, \delta] \) and an induction on \( \ell \) shows that for all \( \ell \in \mathbb{N} \) and all \( x \in [-\delta, \delta] \),

\[ \frac{\phi^{(\ell)}(x)}{\ell!} = (-1)^\ell \sum_{\alpha \in \mathbb{N}^d \atop |\alpha| = \ell} a^\alpha \prod_{j=1}^d \left( \frac{-s_j}{\alpha_j} \right) \prod_{j=1}^d (1-x a_j)^{-s_j-\alpha_j}. \]

The identity (6.2) then follows from the application of the Taylor formula with integral remainder at \( x = 0 \).

The second part of the lemma follows from the theorem of holomorphy under the integral sign. This completes the proof of Lemma 6. \( \square \)

**Proof.** (points 1 and 2 of Theorem 5)

For short, let us write \( Z(s) \) for \( Z_A(E; s) \).

First we remark that if \( a = (a_1, \ldots, a_d) = (0, \ldots, 0) \), then \( E \) is of the form \( E(X) = uX^d \) where \( u > 0 \). It follows that \( Z(s) = d u^{1-\delta} \zeta(ds-d+1) \) and Theorem 5 is true in this case.

We will assume in the sequel that \( a \neq (0, \ldots, 0) \) and set \( \delta = \left( 2 \max_j |a_j| \right)^{-1} > 0 \). We will note in the sequel \( s = \sigma + i \tau \) where \( \sigma = \text{Re}(s) \) and \( \tau = \text{Im}(s) \). It is easy to see that

\[ \left| \frac{E'(n)}{E(n)^s} \right| \ll \frac{1}{n^{d\sigma-(d-1)}}. \]

It follows that \( s \mapsto Z(s) \) converges absolutely in the half-plane \( \{ \text{Re}(s) > 1 \} \).
As the act of removing or adding a finite number of terms does not change the meromorphy or poles, we can choose the integer $A$ as large as possible. Let us choose here $A \in \mathbb{N}^*$ such that $A \geq 2 \sup_{1 \leq j \leq d} |a_j| = \delta^{-1}$.

It is clear that we can also assume without loss of generality that the polynomial $E$ is unitary. It follows that

$$E(X) = \prod_{j=1}^{d} (x - a_j) \quad \text{and} \quad E'(X) = E(X) \left( \sum_{j=1}^{d} \frac{1}{X - a_j} \right).$$

We deduce that for all $s \in \mathbb{C}$ satisfying $\sigma = \Re(s) > 1$ there holds:

$$Z(s) = \sum_{n=A}^{+\infty} \frac{E'(n)}{E(n)^s} = \sum_{n=A}^{d} \sum_{n=A}^{+\infty} \frac{1}{(n - a_j)^s \prod_{k\neq j} (n - a_k)^{s-1}}$$

$$= \sum_{j=1}^{d} \sum_{n=A}^{+\infty} \frac{1}{n^{ds-(d-1)}} \left(1 - \frac{a_j}{n}\right)^{-s} \prod_{k\neq j} \left(1 - \frac{a_k}{n}\right)^{-s+1}.$$

Let $N \in \mathbb{N}$. Lemma 6 and the previous relation imply that for all $s \in \mathbb{C}$ verifying $\sigma = \Re(s) > 1$ we have:

$$Z(s) = \sum_{j=1}^{d} \sum_{n=A}^{+\infty} \frac{1}{n^{ds-(d-1)}} \left[ \sum_{\ell=0}^{N} c_{\ell} \left( f_j(s) \right) \frac{1}{n^{\ell}} + \frac{1}{n^{N+1}} \rho_N \left( x, f_j(s) \right) \right],$$

where $f_j(s) = (s_1, \ldots, s_d)$ with $s_k = s - 1$ if $k \neq j$ and $s_j = s$.

We deduce that for all $s \in \mathbb{C}$ verifying $\sigma = \Re(s) > 1$ there holds:

$$Z(s) = \sum_{\ell=0}^{N} \left[ \sum_{j=1}^{d} c_{\ell} \left( f_j(s) \right) \right] \zeta_A \left( ds - (d - 1) + \ell \right)$$

$$+ \sum_{n=A}^{+\infty} \frac{1}{n^{ds-(d-1)+N+1}} \left[ \sum_{j=1}^{d} \rho_N \left( x; f_j(s) \right) \right], \quad (6.3)$$

where $\zeta_A(s) := \sum_{n=A}^{+\infty} \frac{1}{n^s} = \zeta(s) - \sum_{n=1}^{A-1} \frac{1}{n^s}$. 
On the other hand it is easy to see that for all $\ell \in \mathbb{N}$:

$$
\sum_{j=1}^{d} c_\ell (f_j(s)) = \sum_{j=1}^{d} (-1)^\ell \sum_{\substack{\alpha \in \mathbb{N}^d \\
|\alpha| = \ell}} \alpha^\alpha \left( \frac{-s}{\alpha_j} \prod_{k \neq j} \left( \frac{-s + 1}{\alpha_k} \right) \right)
$$

$$
= \sum_{j=1}^{d} (-1)^\ell \sum_{\substack{\alpha \in \mathbb{N}^d \\
|\alpha| = \ell}} \alpha^\alpha \frac{s + \alpha_j - 1}{s - 1} \prod_{k=1}^{d} \left( \frac{-s + 1}{\alpha_k} \right)
$$

$$
= (-1)^\ell \sum_{\substack{\alpha \in \mathbb{N}^d \\
|\alpha| = \ell}} \alpha^\alpha \prod_{k=1}^{d} \left( \frac{-s + 1}{\alpha_k} \right) \sum_{j=1}^{s + \alpha_j - 1} \frac{d s - d + \ell}{s - 1}.
$$

(6.4)

Relations (6.3) and (6.4) imply that for all $s \in \mathbb{C}$ satisfying $\sigma = \text{Re}(s) > 1$ we have:

$$
(s - 1) Z(s) = \sum_{\ell=0}^{N} \left[ (-1)^\ell \sum_{\substack{\alpha \in \mathbb{N}^d \\
|\alpha| = \ell}} \alpha^\alpha \prod_{k=1}^{d} \left( \frac{-s + 1}{\alpha_k} \right) \right] (ds - d + \ell) \zeta_A (ds - (d - 1) + \ell)
$$

$$
+ (s - 1) \sum_{n=A}^{+\infty} \frac{1}{n^{ds-(d-1)+N+1}} \left[ \sum_{j=1}^{d} \rho_N (x; f_j(s)) \right].
$$

(6.5)

Moreover,

1) the point 2 of lemma 6 and the dominated convergence theorem of Lebesgue imply that

$$
s \mapsto \sum_{n=A}^{+\infty} \frac{1}{n^{ds-(d-1)+N+1}} \left[ \sum_{j=1}^{d} \rho_N (x; f_j(s)) \right]
$$

is defined and is holomorphic in the half-plane $\{ \sigma > 1 - \frac{N+1}{d} \}$;

2) the classical properties of the Riemann zeta function imply that the function

$s \mapsto (s - 1) \zeta_A(s)$ is holomorphic in the whole complex plane $\mathbb{C}$.

These last two points and identity (6.5) implies that $s \mapsto (s - 1) Z(s)$ has a holomorphic extension to the half-plane $\{ \sigma > 1 - \frac{N+1}{d} \}$. As $N \in \mathbb{N}$ is arbitrary, we
deduce that \( s \mapsto (s - 1)Z(s) \) has a holomorphic continuation to the whole complex plane \( \mathbb{C} \).

It follows that \( s \mapsto Z(s) \) has a meromorphic continuation to the whole complex plane \( \mathbb{C} \) with at most one possible simple pole in \( s = 1 \).

So to finish the proof of points 1 and 2 of Theorem 5, it suffices to show that \( s = 1 \) is a pole of residue 1. But relation (6.5) with \( N = 0 \) implies that

\[
\lim_{s \to 1} (s - 1)Z(s) = \lim_{s \to 1} (ds - d)\zeta_A(ds - d + 1) = 1.
\]

We deduce that \( s = 1 \) is a simple pole of \( Z(s) \) and that \( \text{Res}_{s=1} Z(s) = 1 \). This completes the proof of points 1 and 2 of Theorem 5. \( \square \)

PROOF. (point 3 of Theorem 5)

First let us recall the classical formula

\[
k \zeta(1 - k) = (-1)^{k-1} B_k = -\Psi((X + 1)^k) \quad \forall k \in \mathbb{N}^*.
\]  

(6.6)

Let \( M \in \mathbb{N}^* \). Set \( N = dM \). In particular, \( 1 - M > 1 - \frac{N+1}{d} \). If \( |\alpha| = N + 1 \), then for any \( j = 1, \ldots, d \):

\[
\alpha_j > M - 1 \quad \text{or} \quad \text{there exists } k \in \{1, \ldots, d\} \setminus \{j\} \text{ such that } \alpha_k > M.
\]

We deduce that for any \( j = 1, \ldots, d \):

\[
\rho_N \left( x; f_j(1-M) \right) = (-1)^{N+1}(N+1) \sum_{\substack{\alpha \in [d] \\ |\alpha| = N+1}} a^\alpha \left( \frac{M-1}{\alpha_j} \right) \prod_{k \neq j}^d \left( \frac{M}{\alpha_k} \right) \times
\]

\[
\int_0^1 \frac{1}{(1 - t)^N} \left( 1 - t x a_j \right)^{M-\alpha_j} \prod_{k \neq j}^d \left( 1 - t x a_k \right)^{M-1-\alpha_k} dt = 0.
\]

It follows then from (6.5) that

\[
-MZ(1 - M) = \sum_{\ell=0}^N (-1)^\ell \sum_{\substack{\alpha \in [d] \\ |\alpha| = \ell}} a^\alpha \prod_{k=1}^d \left( \frac{M}{\alpha_k} \right) \left( \ell - dM \right) \zeta_A \left( 1 + \ell - dM \right)
\]
\[
\sum_{\ell=0}^{N} (-1)^\ell \sum_{\alpha \in \mathbb{N}^d \atop |\alpha| = \ell} a^\alpha \prod_{k=1}^{d} \binom{M}{\alpha_k} (\ell - dM) \zeta (1 + \ell - dM) \\
- \sum_{\ell=0}^{N} (-1)^\ell \sum_{\alpha \in \mathbb{N}^d \atop |\alpha| = \ell} a^\alpha \prod_{k=1}^{d} \binom{M}{\alpha_k} (\ell - dM) \left( \sum_{u=1}^{A-1} u^{dM-\ell-1} \right).
\]

(6.7)

This sum therefore splits into two parts. Remarking that if \(|\alpha| > N\) then there exists \(k\) such that \(\alpha_k > M\) and hence \(\binom{M}{\alpha_k} = 0\), we can compute the second part:

\[
\kappa := - \sum_{\ell=0}^{N} (-1)^\ell \sum_{\alpha \in \mathbb{N}^d \atop |\alpha| = \ell} a^\alpha \prod_{k=1}^{d} \binom{M}{\alpha_k} (\ell - dM) \left( \sum_{u=1}^{A-1} u^{dM-\ell-1} \right)
\]

\[
= \sum_{u=1}^{A-1} u^{dM-1} \sum_{\ell=0}^{N} \sum_{\alpha \in \mathbb{N}^d \atop |\alpha| = \ell} (dM - \sum_{j=1}^{d} \alpha_j) \left[ \prod_{k=1}^{d} \binom{M}{\alpha_k} \left( - \frac{a_k}{u} \right)^{\alpha_k} \right] \\
= \sum_{u=1}^{A-1} u^{dM-1} \sum_{\alpha \in \{0, \ldots, M\}^d} (dM - \sum_{j=1}^{d} \alpha_j) \left[ \prod_{k=1}^{d} \binom{M}{\alpha_k} \left( - \frac{a_k}{u} \right)^{\alpha_k} \right].
\]

(6.8)

Continuing this computation by splitting this sum in two, we have

\[
\kappa = dM \sum_{u=1}^{A-1} u^{dM-1} \prod_{k=1}^{d} \left( 1 - \frac{a_k}{u} \right)^{M} - \sum_{u=1}^{A-1} \sum_{j=1}^{d} u^{dM-1} \frac{(-a_j)}{u} \prod_{k=1}^{d} \left( 1 - \frac{a_k}{u} \right)^{M} = \]

\[
= dM \sum_{u=1}^{A-1} u^{-1} E(u)^{M} + M \sum_{u=1}^{A-1} \sum_{j=1}^{d} \frac{a_j}{u(u-a_j)} E(u)^{M} = \]

\[
= M \sum_{u=1}^{A-1} E(u)^{M-1} E'(u). \quad (6.9)
\]
Relations (6.6), (6.7), (6.8) and (6.9) imply that
\[
Z(1 - M) = \frac{(-1)^{dM - 1}}{M} \sum_{\ell = 0}^{N} \left[ \sum_{\alpha \in \mathcal{V}} \prod_{k=1}^{dM} \binom{M}{\alpha_k} \right] B_{dM - \ell} - \sum_{u=1}^{A^{-1}} E(u)^{M-1} E'(u).
\]

(6.10)

On the other hand, it is easy to see that
\[
E(X)^M = \prod_{j=1}^{d} (X - a_j)^M = \prod_{j=1}^{d} \left( \sum_{\alpha_j = 0}^{M} \binom{M}{\alpha_j} (-a_j)^{\alpha_j} X^{M-\alpha_j} \right) =
\]

\[
= \sum_{\alpha \in \{0, \ldots, M\}^d} (-1)^{\left| \alpha \right|} \prod_{j=1}^{d} \binom{M}{\alpha_j} X^{dM - \left| \alpha \right|} =
\]

\[
= \sum_{\ell = 0}^{N} (-1)^{\ell} \left[ \sum_{\alpha \in \mathcal{V}^{\ell}} \prod_{j=1}^{d} \binom{M}{\alpha_j} \right] X^{dM - \ell}.
\]

Using (6.1), it follows that
\[
\Psi(E(X + 1)^M) = (-1)^{dM} \sum_{\ell = 0}^{N} \left[ \sum_{\alpha \in \mathcal{V}^{\ell}} \prod_{j=1}^{d} \binom{M}{\alpha_j} \right] B_{dM - \ell}.
\]

We then deduce from (6.10) that
\[
Z(1 - M) = -\frac{1}{M} \Psi(E(X + 1)^M) - \sum_{u=1}^{A^{-1}} E(u)^{M-1} E'(u).
\]

This completes the proof of Theorem 5.
